## Bell-Nonlocal Quantum Entanglement as Boundary-Level Compatibility

Amos Jay Maley

2026

### Revision status

This publication revision is designated v0.19.0. It performs the bounded correctness closure requested after the final referee audit while preserving the strong endpoint: primitive same-target candidacy, together with the activated kernel and exact imported closure spine, forces one boundary-compatible target-bearing governance form up to extensional governance equivalence.

### Typed act support

The prior support expression mixed a proposition with a value. The revised interface defines  $\text{SameActSupport}_{\mathcal{B}}(\Phi)$  as equality of endpoint support labels and defines  $\text{ActSupp}_{\mathcal{B}}(\Phi)$  as the typed value in  $\{A, B, AB\}$ . One-wing support requires both the equality condition and the corresponding typed value.

### Canonical compatibility continuation

The canonical raw compatibility datum now carries the active continuation relation  $\mathcal{K}_{\mathcal{P}}^{\text{act}}$ , rather than the unrestricted reference relation. The compatibility certificate therefore applies directly on the active reuse carrier, and continuation-equivalence reflexivity supplies its C5 requirement.

### Retyping and metric authority

The no-cost-free-retyping proof now distinguishes preservation of the reference-bearing target from governance-inert presentation skin. A proposal preserving the target remains a same-target proposal for the standing, continuation, temporal, and reuse classifications. The metric-authority proof now uses semantic effect exhaustion, no-second-invariant rigidity, the AMetric no-selector theorem, and same-scope operator closure to exclude metric metadata as an independent discriminator in every governance channel, not only at anchor admission.

### Formalization boundary

No new Lean theorem is claimed. The released v0.8.0 repository remains controlling for the finite denominator-32 carrier and conditional endpoint bridge. The v0.19.0 corrections remain manuscript-level results.
